Introduction

Unique aspects of intraoperative neuromonitoring (IONM) and mapping (IONMa) apply to tethered cord surgery:

- Not all cases require SSEP monitoring.
- Accurate EMG interpretation depends on the equipment and methodology used.

There is no consensus on what MEP amplitude decrease should be alert criteria.

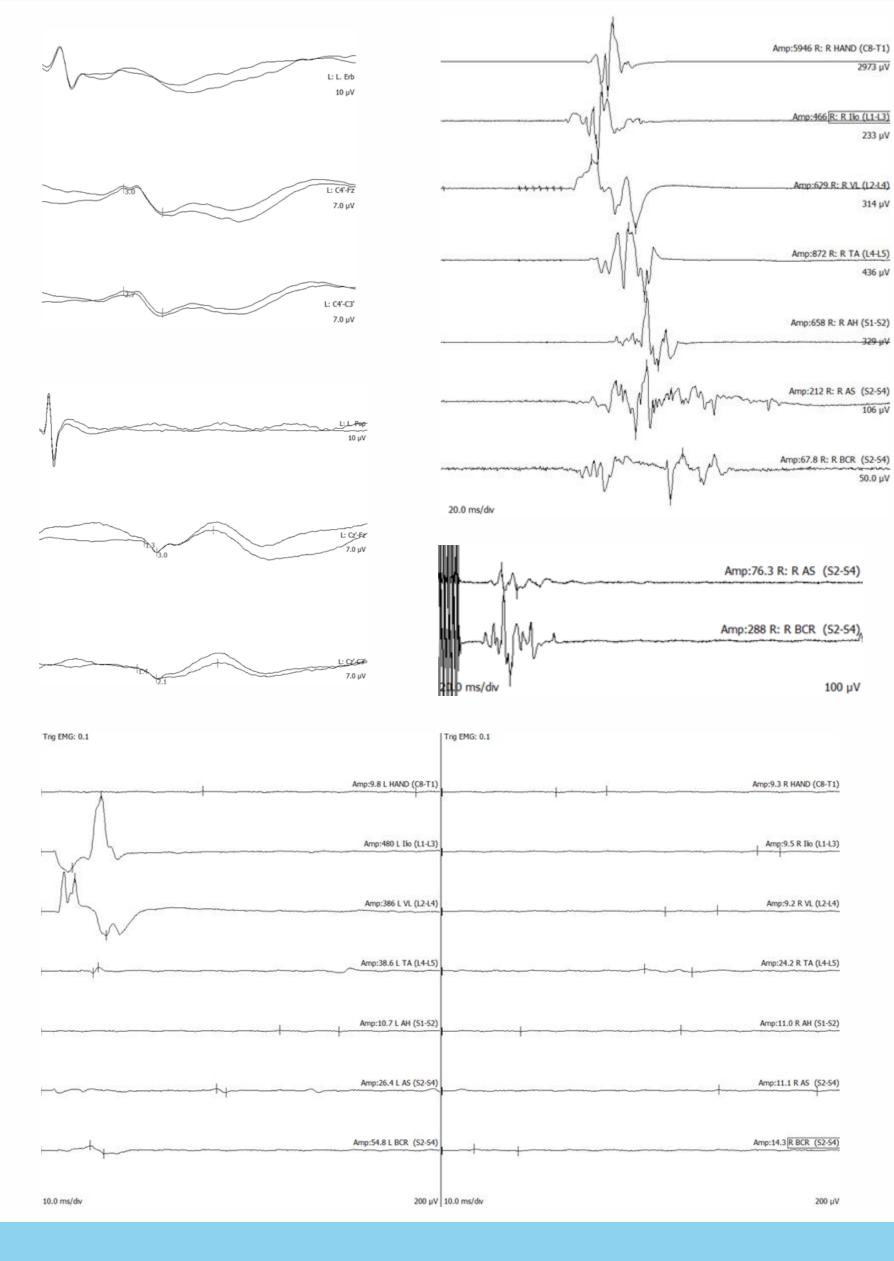

Stimulation techniques and equipment used vary.

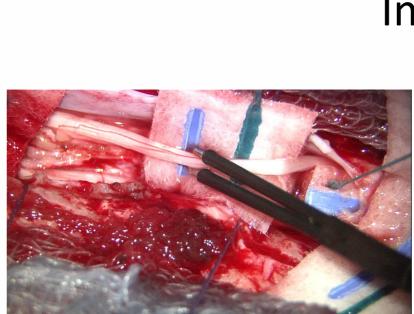

• Incomplete myelination in young children could prevent consistent IONM.

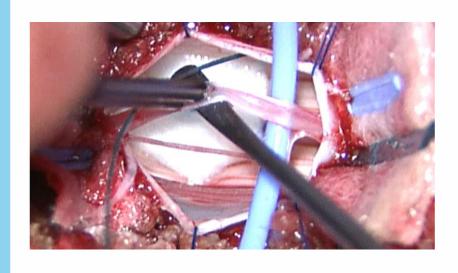

Therefore, additional observational studies reporting IONM/IONMa utility in paediatric tethered cord surgery are still required.

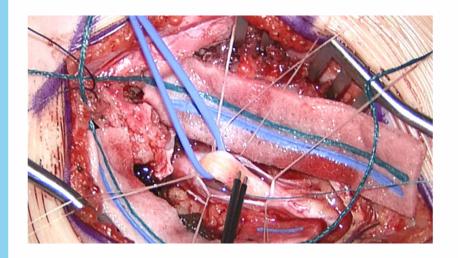

We report on IONM/IONMa feasibility, alert criteria employed, measures taken to prevent postoperative injury, and patient outcome, with particular attention to our institution's monitoring and mapping methodology.

Images

igure 1: Bipolar stimulation techniqu Both anode and cathode (silver poles) re in continuity with the structure to be stimulated and attempts are made to solate the structure from surrounding erebrospinal fluid and adjacent conductive tissue. Response from muscle t 0.1mA stimulation intensity

structure thought to be the filum. No response >10mA stimulation intensity.

Figure 3: Bipolar stimulation of structure thought to be the filum. Response at 4.5mA stimulation intensity: further dissection/exploration warranted.

Figure 4: On exploration, rootlet found tethered to the ventral aspect of filum (asterisk).

Key findings

BCR monitorability is associated with gender and lipoma type. Alert criteria breaches are associated with

lipoma type.

Figure 5: Preoperative signs/symptoms of patients with tethered cord, grouped as improved, stabilised, or worsened postoperatively.

Testing for nerve roots adhered to the filum prior to disconnection is essential to avoid neurological injury.
